

MYTH

Milk contains antibiotics

TRUTH

There will never be any antibiotics in your milk. Milk is tested multiple times before it gets to you, and if it tests positive for even the slightest amount of antibiotics, it is safely thrown out and never reaches the store.

Both organic and conventional dairy farmers treat sick cows with the same antibiotics under the close supervision of a veterinarian.

- On a conventional farm, the cow is taken from the milking herd for treatment, and not returned to the herd until her milk tests free of antibiotics.
- On an organic farm, that cow permanently leaves the herd, and is usually moved to a conventional dairy farm.

MYTH

There are harmful hormones in milk

TRUTH

Hormones are naturally present in all foods, whether plant or animal, and are broken down during digestion. Both conventional and organic milk naturally contain tiny amounts of hormones – an extremely low amount relative to the amount our bodies naturally produce.

Bovine somatotropin (bST) is a protein hormone that cows naturally produce to grow as calves and make milk as adults. Scientists have made a copy of bST called recombinant bovine somatotropin (rbST), which some dairy farmers choose to give to cows to boost milk production. rbST is never added directly to milk.

- Health authorities such as the Food and Drug Administration (FDA) and the National Institutes of Health (NIH) have found that milk from cows treated with rbST is both nutritious and safe.
- Research shows the hormone levels in milk are the same whether or not cows are given rbST.¹

MYTH

Milk causes early puberty

TRUTH

Some studies suggest puberty has been skewing younger over several decades,² but children's milk consumption has declined over the same period.³ The potential causes and long-term effects of early puberty remain unclear, but recent studies suggest it may be linked with higher body weight.⁴

MYTH

Dairy cows are mistreated

TRUTH

Dairy farmers' commitment to providing high-quality milk begins with taking good care of their cows.

- Dairy cows have balanced, nutritious diets designed by professional nutritionists.
- Dairy cows have access to clean water all day.
- Dairy cows receive preventive veterinary care and prompt treatment when they're sick
- Many dairy cows live in freestall barns that protect them from the weather while allowing them to walk around, eat, drink and sleep whenever they choose.

MYTH

Pasteurization destroys the nutrients in milk

TRUTH

Pasteurized milk offers the same health benefits as raw milk, without the risks.

- A small amount of vitamin C is lost during pasteurization, however, milk is not a good source of vitamin C to begin with.
- · Bad Bacteria that can cause harm is destroyed during pasteurization. If you are looking for good bacteria, like probiotics, yogurt and kefir are good dairy sources; these are made from pasteurized milk without the risk of foodborne illness.

The U.S. Centers for Disease Control and Prevention (CDC) and the U.S. Food and Drug Administration (FDA) recommend that no one consume raw milk.
